

PHASE 5 – PROJECT DEVELOPMENT AND IMPLEMENTATION

Project Title

Script-Controlled ACL – Restrict Record Access Based on Field Value

1. Implementation Overview

The project was implemented in the ServiceNow platform to provide controlled access to records. The access permission is determined by the value stored in a specific field.

2. System Configuration

The required ServiceNow table and records were configured for the project. An ACL was created to manage access permissions for the selected records.

3. Script Development

A JavaScript-based script was added to the ACL. The script checks the required field value and determines whether the user should be permitted to access the record.

4. Access Control

When the field value satisfies the defined condition, access is granted. If the condition is not satisfied, access to the record is restricted.

5. Validation

The implemented functionality was checked using different record values and user access conditions. The results were observed to ensure that the access control works according to the defined requirements.

6. Implementation Result

The Script-Controlled ACL was implemented successfully in ServiceNow. The system can control record access based on field values and provides an additional layer of record security.
